Genet. 106:321-329(2000).

Hum. Genet. 106:321-329(2000).

PUNCTION: One gap junction consists of a cluster of closely packe pairs of transmembrane channels, the connexons, through which materials of low mw diffuse from one cell to a neighboring cell.

SUBCELLULAR LOCATION: Integral membrane protein.

IDISEASE: Defects in GUBB are a cause of erythrokeratedermia variabilis (EKV) [MIM:133200], an autosomal dominant disease characterized by 2 morphologic features: transient figurate red patches and localized or generalized hyperkeratosis.

DISEASE: Defects in GUBB are a cause of autosomal dominant non-syndromic sensorineural deafness type 2 (DFNA2) [MIM:600101].

SUBDILARITY: BELONGS TO THE CONNEXIN FAMILY. BETA-TYPE (GROUP I)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            MEDLINE=20256220; PubMed=10798362; Richard G., Brown N., Smith L.E., Mackie R.M., Bale S.J., Uitto J.;

Chang S., Nicholson B.J., Willecke K.;

Two gap junction genes, connexin 31.1 and 30.3, are closely linked or mouse chromosome 4 and preferentially expressed in skin.";

J. Biol. Chem. 267:17225-17233 (1992).

C -i- FUNCTION: One gap junction consists of a cluster of closely packed pairs of transmembrane channels, the connexons, through which materials of low mw diffuse from one cell to a neighboring cell.

C -i- SUBCINIT: A connexon is composed of a hexamer of connexins.

C -i- SUBCILULAR LOCATION: Integral membrane protein.

C -i- SINGCILULAR LOCATION: Integral membrane protein.

C -i- SINGLELULAR SECONGS TO THE CONNEXIN FAMILY. BETA-TYPE (GROUP I)

C SUBFRAMILY: BELONGS TO THE CONNEXIN FAMILY. BETA-TYPE (GROUP I)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Matches

RI Submitted (NOV-1997) to the EMBL/GenBank/DDBJ databases.

CC -!- FUNCTION: Binding to cells via a high affinity receptor, laminin conformation of cells into tissues during embryonic development by interacting converted to the extracellular matrix components.

CC -!- FUNCTION: ALPHA-5 CHAIN MAY BE THE MAJOR LAMINIAE.

CC -!- SUBUNIT: Laminin is a complex glycoprotein, consisting of three confiderent bolypeptide chains (alpha, beta, gamma), which are bound to each other by disulfide bonds into a cross-shaped molecule comprising one long and three short arms with globules at each
